#### Want to test:

- Evaluate usability and available diagnostics
- Intra-night consistency
  - Use observations on the same baseline throughout the night
- Night-to-night consistency
  - Use observations on the same baseline between nights.
- Compare pipeline nominal value and uncertainty estimates
- Verify reliability of reductions

### **Pipeline error predictions**

### **Differences between pipelines**

# Conclusions

- Both pipelines produce similar nominal values for low flux objects.
- TTB pipeline:
  - Uncertainties extremely scattered, often conservative
  - Minimum uncertainties seem too good
  - Needs a few improvements, easily scripted, easy to use
  - Pipelines working for both CLASSIC and CLIMB
- JDM pipeline:
  - Uncertainties similar throughout a night
  - Minimum uncertainties clearly enforced
  - Many more diagnostic screens, easy to use
  - No CLIMB pipeline (yet)
- Comparison suggests minimum  $\sigma V^{_2} \sim 0.01 0.02$  for  $V^{_2} < 0.3$
